Abstract

Our study pertains to evaluate the protective effect of selenium (Se), used as a nutritional supplement, against aluminium chloride induced cardiotoxicity in rats. Rats have received during 21 days either AlCl3 (400 ppm) via drinking water, AlCl3 associated with Na2SeO3 (0.5 mg/kg of diet) or only Na2SeO3. Co-administration of Se to AlCl3 treated rats alleviated heart oxidative stress objectively by a decrease of malondialdehyde, hydrogen peroxide and protein carbonyls levels. An improvement in antioxidant redox status, enzymatic (catalase, superoxide dismutase and glutathione peroxidase) and non enzymatic (reduced glutathione, non protein thiols and vitamin C) was also observed in Se treated rats. LDH and CK activities, TC, LDL-C levels, TC/HDL-C and LDL-C/HDL-C ratios were increased, while HDL-C and TG decreased in rats treated with AlCl3. Cardiac biomarkers and lipid profile were restored to near control values by the supplementation of Se. Our results revealed that Se, a trace element with antioxidant properties, was effective in preventing heart damage induced by aluminium chloride.

Keywords: Aluminium, rats, oxidative stress, selenium, heart

Introduction

Aluminium (Al) is broadly dispersed throughout the natural and industrial environment (1). It is widely used in daily life causing its easy exposure to animals and human beings. Al sources are mainly corn, yellow cheese, salt, herbs, spices, tea, cosmetics, ware, and containers. It has been reported that Al could accumulate in all tissues of animals, preferentially in liver, heart, bones and brain (2). This metal disrupts the pro-oxidant/antioxidant balance in tissues leading to biochemical and physiological dysfunction due to an excessive reactive oxygen species (ROS) generation (3,4). Chronic aluminium exposure results in a decreased activity of complexes I, II and IV of electron transport chain leading to the impairment of mitochondrial energy metabolism and oxidative damage (5). Oxidative stress may play a crucial role in cardiac and vascular abnormalities in different types of cardiovascular diseases (6). The mechanism by which Al produces cardiotoxicity effects may be attributed to oxidative stress and disturbance of the intracellular redox system. Supplementation of antioxidants can be considered as an alternative method to alleviate metals induced oxidative heart damage. Selenium (Se) is generally recognized to be a trace element of great importance for human health which protects the cells from the harmful effects of free radicals attack (7). Previous studies have confirmed the protective effects of Se against free-radical induced cardiac injury (8,9). It plays an important role in many physiological processes including the biosynthesis of coenzyme Q, regulation of ion fluxes across membranes and stimulation of immune function (10). The beneficial effect of Se is attributed to selenoproteins such as glutathione peroxidase and thioredoxin reductase.

The underlying mechanisms of Al-induced toxicity are not entirely clear; however, they are apparently related to its pro-oxidant effects. To our knowledge, findings concerning the cardiotoxic effects of Al remain scarce and appear to be lacking. In an effort to better our understanding on aluminum heart toxicity mechanism, the present study was designed to explore whether the administration of this metal induced heart tissue damage in adult rats and to evaluate the possible ameliorative effect of Se.

Materials and methods

Chemicals

Aluminium Chloride (AlCl3), selenium (Na2SeO3), glutathione (oxidized and reduced),
nicotinamide adenine dinucleotide phosphate reduced form (NADPH), 5, 5′-dithiobis-2-nitrobenzoic acid (DTNB) and thiobarbituric acid (TBA) were purchased from Sigma (St. Louis; MO, USA). All other chemicals, of analytical grade, were purchased from standard commercial suppliers.

Animals and treatment
Female Wistar rats, weighing 160 ± 10 g, were obtained from the Central Pharmacy (SIPHAT, Tunisia). They were housed at ambient temperature (22 ± 2 °C) in a 12-h light/dark cycle and a minimum relative humidity of 40%. Food (SNA, Sfax, Tunisia) and water were available ad libitum. One week after acclimatization to laboratory conditions, the rats were randomly divided into four groups of six each. Animals were treated for a period of 21 days as follows: group I, serving as negative control, received standard diet and distilled water; group II received via drinking water AlCl₃ (50 mg/kg bw); group III received both AlCl₃ and Se (0.5 mg/Kg of diet) and group IV, serving as a positive control, received Se as sodium selenite (Na₂SeO₃) at a dose of 0.5 mg/kg of diet. The dose of selenium (0.5 mg/kg of diet) used in our study and in other findings gave high protection against stress conditions in several tissues (11,12). The dose of aluminium chloride (50 mg/kg bw) used in our experiment, which corresponded to 1/8 of LD50 was chosen according to Allagui et al. (13). At the end of the experimental period, animals were killed by cervical decapitation to avoid stress. Blood was collected into heparinized tubes and centrifuged at 2200×g for 10 min. Plasma samples were drawn and stored at -80°C until analysis. Hearts were dissected out, cleaned, homogenized in a Tris·HCl buffer (pH = 7.4) and centrifuged. The resulting supernatants were kept at -80°C for biochemical assays. Approval for rat experiments was obtained from the ethical Committee at Sciences Faculty of Sfax with ethics approval number 1204 and all the experimental procedures were in accordance with the International Guidelines for Animal Care (14).

Biochemicals assays

Protein quantification
Heart protein contents were measured according to the method of Lowry et al (15) using bovine serum albumin as standard.

Heart malondialdehyde (MDA) measurement
The extent of lipid peroxidation by measuring thiobarbituric acid reactive substances (TBARS) in terms of malondialdehyde (MDA) formation was measured according to the method of Draper and Hadley (16). The malondialdehyde values were calculated using 1, 1, 3, 3-tetraethoxypropane as standard and expressed as nmoles of MDA/mg protein.

Hydrogen peroxide (H₂O₂) measurement
Measurement of hydrogen peroxide (H₂O₂) was carried out according to Ou and Woff (17) method. The amount of H₂O₂ produced was determined using the extinction coefficient of 2.67 × 10⁻³ cm⁻¹ M⁻¹ and results were expressed as nmoles/mg protein.

Heart PCO levels
Protein carbonyls (PCO) were measured using the method of Reznick and Packer (18). The carbonyl content was calculated based on the molar extinction coefficient of DNPH (ε = 2.2×10⁴ cm⁻¹ M⁻¹) and expressed as nmoles/mg protein.

GSH, NPSH and vitamin C levels
GSH levels in the heart were determined by the method of Ellman (19) modified by Jollow et al (20). Total GSH content in the heart was expressed as µg/mg of protein. Non protein thiol (NPSH) levels were determined by the method of Ellman (19). The total NPSH content was expressed as nmol/mg of protein. Ascorbic acid determination was performed as described by Jacques-Silva et al (21). The data were expressed as µmoles of ascorbic acid/mg of protein.

Heart enzymatic antioxidant activities
Catalase (CAT) activity was determined by the method of Aebi (22) using hydrogen peroxide (H₂O₂) as substrate. A decrease in absorbance due to H₂O₂ degradation was monitored spectrophotometrically at 240 nm for 1 min and the enzyme activity was expressed as µmoles H₂O₂ degraded/min/mg protein. Glutathione peroxidase (GPx) activity was measured according to Flohe and Gunzler (23). The enzyme activity was expressed as nmoles of GSH oxidized/min/mg protein Superoxide dismutase (SOD) activity was estimated according to Beauchamp and Fridovich (24).
Selenium alleviates aluminium cardiotoxicity

Its optical density was measured at 560nm. Units of SOD activity were expressed as the amount of enzyme required to inhibit the reduction of NBT by 50% and the activity was expressed as Units /mg of protein.

**Plasma lipid profile**

Triglycerides, total cholesterol and HDL-Cholesterol levels in plasma were determined using kits from Biomaghreb (Tunisia, 20131, 20111, 20113) respectively. The LDL-Cholesterol fraction and atherogenic index (AI) were determined according to the Friedewald equations (25).

\[
[LDL-Cholesterol] = \text{Total cholesterol} - [\text{Triglyceride} /5 + \text{HDL-Cholesterol}]
\]

\[
AI = (TC - \text{HDL}-C) / \text{HDL}-C
\]

TC/HDL-C and LDL-C/HDL-C ratios were also calculated.

**Biomarkers of cardiotoxicity**

Plasma and heart Lactate dehydrogenase (LDH) and plasma creatine kinase isoenzyme (CK-MB) activities were determined according to standard methods by using diagnostic kits from Biomaghreb (Tunisia, Ref 20012, 20049 and 20063 respectively).

**Statistical analysis**

The data were analyzed using the statistical package program Stat view 5 Software for Windows (SAS Institute, Berkley, CA). Statistical analysis was performed using one-way analysis of variance (ANOVA) followed by Fisher’s protected least significant difference (PLSD) test as a post hoc test for comparison between groups. Student unpaired t-test was also used when comparison between two groups was required. All values were expressed as means ± S.D. The 0.05 level was selected as the point of minimal statistical significance.

**Results**

**Estimation of MDA, PCO and \( H_2O_2 \) levels**

A significant increase in MDA (+69%), \( H_2O_2 \) (+85%) and PCO (+36%) levels was observed in the heart of \( AlCl_3 \) treated rats (Table 1). Co-administration of selenium via diet restored these parameters to near control values (p < 0.001).

**GSH, NPSH and vitamin C levels**

A significant decrease of GSH, NPSH and vitamin C levels (17, 34 and 22%) in the cardiac tissue of \( AlCl_3 \) group was observed when compared to those of controls. These modifications were significantly improved after co-administration of Se which reached control values (Table 2).

**Heart enzymatic antioxidant status**

Antioxidant enzyme activities of CAT, GPx and SOD of control and treated groups are represented in Figure 1.

\( AlCl_3 \), \( (AlCl_3 + Se) \) and Se groups vs control group: *P<0.05; **P<0.01; ***P<0.001.

\( AlCl_3 + Se \) vs \( AlCl_3 : ^{+++} P<0.001. \)

\( AlCl_3 \) treatment resulted in a significant decrease (P < 0.001) in the activities of these enzymes by 47, 42 and 49% when compared to those of control group. Treatment with Se improved the activities of antioxidant enzymes without reaching control values (p<0.001).
Biomarkers of cardiotoxicity

LDH activity in AlCl₃ group was decreased in the heart by 45% while it increased in plasma by 70%, when compared to those of controls indicating the occurrence of heart injury (Figure 2). A significant increase in the activity of plasma CK was also observed following aluminium treatment. Co-administration of Se in the diet restored the values of LDH and CK activities (Figure 2).

Effects of AlCl₃ on lipid profile

In AlCl₃ treated rats, there was an increase in the levels of TG (11%), TC (20%) and LDL-C (23%) and a decrease in TG (13%) and HDL-C (41%) levels.

TC/HDL-C and LDL-C/HDL-C ratios and AI were increased by 93, 105 and 135% respectively when compared to controls (Table 3). Supplementation of Se in the diet of AlCl₃ treated rats improved the parameters cited above.

Discussion

The mitochondrion is the primary intracellular sites of oxygen consumption, whose function is closely linked to the maintenance of redox balance. An imbalance between the overproduction of reactive oxygen species (ROS) and elimination of free radicals induces oxidative stress.
Aluminium toxicity involves oxidative damage playing an imperative role in biochemical alterations. In the present study, exposure of rats to Al through drinking water resulted in a significant increase in lipid and protein oxidation in the heart tissue as evidenced by the significant increase in MDA and PCO levels. According to Nehru and Anand (26), the increase in free intracellular Fe^{2+} causes the peroxidation of lipids and membrane damages in aluminium-treated rats. Lipid peroxidation and production of ROS are the main molecular mechanisms of Al-induced cell damage (27, 28). ROS, including H_{2}O_{2}, generated probably by Al treatment induced a rise of hydrogen peroxide (H_{2}O_{2}) levels suggesting the dysfunction of the mitochondrial respiration chain. The increase of these parameters was well mitigated close to normal levels by the supplementation of selenium. It has been reported to be a protector against lipid peroxidation and useful in the management of myocardial injury (29).

As a consequence of lipid peroxidation, biological membranes are affected leading to the loss of their fluidity and an increase of their permeability leading to the leakage of enzymes. In this regard, lactate dehydrogenase (LDH) and creatine kinase (CK) are considered as the reliable markers of cardiac damage. Several studies have consistently reported the elevated activities of these enzymes in the serum of experimental animals immediately after myocardial infarction (30). Our results showed that CK and LDH activities in the plasma of Al treated rats were clearly increased while LDH decreased in the cardiac tissue confirming the loss of membrane permeability and myocardial injury. Selenium prevented the leakage of LDH and CK from the heart to the extracellular compartment due to its powerful antioxidant potential ensuring the stabilization of membrane.

An antioxidant defense system, mainly involved in scavenging ROS prevents oxidative stress. Antioxidant enzymes, like SOD, CAT and GPx, are recognized as the primary cellular defense against free radical-mediated oxidative stress. In the current study, the homeostasis of antioxidant defenses was altered, as shown by a significant decrease in the activities of these enzymes. Our results were in accordance with the previous reports of Azad et al (31) who have shown an increase in myocardial malondialdehyde level and a decrease in antioxidant enzyme activities after aluminium phosphide treatment. When oxidative stress is in excess, the non-enzymatic antioxidant system like GSH, NPSH and vitamin C complements the activity of the enzymatic antioxidant system. Thiol based antioxidant system plays a second line of cellular defense against free radicals and other oxidant species mediated oxidative damage. In the present study following aluminium treatment, cardiac glutathione redox status was greatly impaired, as indicated by a significant decrease in the levels of GSH and NPSH. Because GSH is involved in recycling vitamin C by mediating the reduction of dehydroascorbate, (32) the GSH deficiency would be expected to reduce the vitamin C levels in the heart of treated rats. Treatment with selenium could react against Al induced oxidative stress in the heart, due to its anti-oxidative potential. Oxidative stress induced by Al caused disturbances in cellular functions and induced a defect in the synthesis and secretion of lipoproteins of the heart. Lipids are thought to be among the most sensitive biological molecules in terms of ROS susceptibility. The increase in the level of total cholesterol in Al treated rats may be due to an increased cholesterol synthesis in the liver (33). Low density lipoprotein-cholesterol (LDL-C) increased, while high density lipoprotein-cholesterol (HDL-C) decreased, suggesting that the abnormal activities of lipase enzymes seem to be one of the chief factors responsible for the cholesterol rise in serum. Our data showed that exposure rats to AlCl_{3} increased significantly LDL-C/HDL-C and TC/HDL-C ratios, considered by Reaven et al (34) as the pertinent indices.

of cardiovascular risk incidence (atherosclerotic index). The supplementation of Se to AlCl₃ treated rats restored the changes of lipid profile near control values. In fact, Se acts as an antioxidant and inhibits the oxidative processes of lipids and lipoproteins in cell membranes (35).

Conclusion
In the present study, oxidative stress induced by Al in the heart tissue of rats might be responsible for the disruption of antioxidant status, oxidation of lipids and proteins and disturbance of lipid profile. Co-administration of Se can mitigate the toxic effects of aluminium by restabilization of the cell membranes, decreasing the levels of cardiotoxicity biomarkers and improvement of the redox state. Our results reflected that Se could be used as an effective supplement in the appropriate management of Al toxicity.
