### Abstract

Today diabetes is one of the most common diseases in the world that affects half of the world population. The use of medicinal herbs especially green tea and cinnamon has been taken into consideration for relieving the symptoms of diabetes, but there were some different ideas about their effectiveness. So, this study was conducted to evaluate the effect of cinnamon and green tea extract, individually and in combination, on blood glucose and weight loss in diabetic mice with Streptozotocin (STZ). The experiment was performed on 50 Wistar rats. A total of 50 rats were divided into 10 groups of 5 and STZ was injected at the dose of 40 mg/kg/day for 5 days intraperitoneally. After diabetes induction, three groups received, 50, 100 and 200 mg doses of green tea extract, three groups received 50, 100 and 200 mg doses of cinnamon extract and three final groups received 50, 100 and 200 mg doses of cinnamon and green tea in combination by gavages daily for 6 weeks. After each period of treatments, blood glucose and the weight of animals were determined. At the end of the sixth week, blood glucose and weight loss were improved in diabetic rats in a dose-dependent manner and the dose of 200 mg/kg extract cinnamon with green tea had the most appropriate synergic effect.

**Keywords:** Cinnamon, green tea, diabetes, streptozotocin.

### Introduction

Diabetes mellitus (DM) is a group of metabolic diseases in which a person has high blood sugar with symptoms of frequent urination, increased thirst, increased hunger and weight loss. Untreated, diabetes can cause many complications as diabetic Ketoacidosis and nonketotic hyperosmolar coma (1). Today, diabetes is one of the most common diseases in the world that affects half of the world population. Every 30 seconds, one

person in the world loses a leg due to lack of awareness of diabetes and diabetes controls (2, 3). Serious long-term complications include heart disease, kidney failure and damage to the eyes. Diabetes is due to either the pancreas not producing enough insulin or cells of body not respond properly to the insulin. Insulin is the principal hormone that regulates uptake of glucose from the blood into most cells (primarily muscle and fat cells, but not

\* E-mail: [raminataee1349@gmail.com](mailto:raminataee1349@gmail.com)

central nervous system cells) (2). Therefore, deficiency of insulin or the insensitivity of its receptors plays a central role in all forms of diabetes mellitus (2). Diabetes mellitus is a chronic disease, for which there is no known cure except in very specific situations (3). Management concentrates on keeping blood sugar levels as close to normal ("euglycemia") as possible, without causing hypoglycemia. This can usually be accomplished with diet, exercise, and use of appropriate medications (insulin in the case of type 1 diabetes; oral medications, as well as possibly insulin, in type 2 diabetes) (3).

A number of medicinal/culinary herbs have been reported to yield hypoglycemic effects in patients with diabetes. Cinnamon has been shown to potentiate the insulin effect through upregulation of the glucose uptake in cultured adipocytes (4). Also, there are some controversial reports about role of green tea in diabetes (4,5). Some reports approved its' beneficial effect in diabetes and in some it is in doubt, for example, Ryu et al approved the effects of green tea on inflammation and arterial stiffness in diabetes patients. As results of their study, inflammatory markers, such as CRP and IL-6, were unchanged after green tea consumption, and neither were blood glucose, lipid profiles, insulin resistance, or serum adiponectin levels (5).

Although there were some literatures which show beneficial role of green tea and cinnamon in diabetes, these were not enough studies especially any precise study showing the effect of combinational treatment regime of these herbs in vivo; so, we have aimed this study to evaluate and compare the effect of these herbal extracts individually and in combination in animal model of diabetes type 1.

## Materials and methods

### Materials

Streptozotocin, aluminum chloride ( $\text{AlCl}_3$ ) and KOH were purchased from Merck Company (Germany). UV/V is VARIAN@50-SCAN spectrophotometer (Italy) and 1cm quartz cells were used for all absorbance measurements. Levels of blood glucose were measured by Randox kits (Germany) and with Glucometer (Apocheck, Germany).

### Plant material

We provided specified grade of green tea (*Camellia sinensis* L.) from Lahijan (Iran) and cinnamon wood (*Cinnamomum verum*) from India (Raja Co, Mumbai). Hydroalcoholic extracts were prepared by percolation (7). Briefly, 200 grams of *Cinnamomum verum* stems and 200 grams *Camellia sinensis* L. leaves were milled, and extracted by maceration method with methanol. Extraction procedure was performed three times with an interval of 48 hours. The provided extracts were concentrated by rotary, and finally were dried completely using freeze dryer machine. After extraction with methanolic solvent, the resulting residues were extracted by water solvent, separately (8,9).

### Determination of the total flavonoid

For flavonoid determination of extract, aluminum chloride method was used. In this method quercetin (Sigma, Germany) was used as the standard and flavonoid contents were measured as quercetin equivalent. For this purpose, the calibration curve of quercetin was drawn (Figure 1). 0.5 mL of standard solution (15, 30, 60, 125 and 250  $\mu\text{g/ml}$ ) was taken into tubes, containing 1.5mL ethanol. 0.1mL of KOH 1M was added to the flask. After 5min, 0.1mL 10%  $\text{AlCl}_3$  and 2.8 mL of distilled water were added to the mixture. The

absorbance was noted at 415 nm using UV-Visible spectrophotometer (12).

#### *Animals and treatment*

All procedures for animal workings have confirmed by Ethical committee of Deputy of Research, Mazandaran University of Medical Sciences (the number of project: 92-43). A total of 50 rats (5-6 weeks), 225-250 g, originated from Albino race, were obtained from the Animals Laboratory Institute of Mazandaran University of Medical Sciences (Sari, Iran). The animal room temperature was  $23 \pm 2$  °C, with a relative humidity of 55% and a 12 h day-night cycle. Housing, breeding and treatment of rats were in accordance with national and institutional guidelines (10). A total of 50 rats were divided into 10 groups of 5 animals each. STZ was injected at dose of 40 mg/kg/day for 5 days intraperitoneally (4). Two weeks later, three groups received 50, 100 and 200 mg doses of green tea extract dissolved in dimethyl sulfoxide (DMSO) 10% by gavages daily for 6 weeks, respectively (16).

The other three groups were dosed daily 50, 100 and 200 mg cinnamon extract by gavage for 6 weeks, respectively, and three final groups received 50, 100 and 200 mg doses of cinnamon with green tea extract daily by gavages for 6 weeks, respectively. During the study period, animals were maintained in standard laboratory conditions (temperature 22 °C and light period - 12 h darkness). All data were analyzed using Student t-test and one-way ANOVA and for  $EC_{50}$  by Chi-Square(11).

#### *Determination of the Total Flavonoid*

For flavonoid determination of extract, Aluminum chloride method was used. In this method, quercetin (Sigma, Co. Germany), was used as the standard and flavonoid contents were measured as

quercetin equivalent. For this purpose, the calibration curve of quercetin was drawn (Figure 1). 0.5ml of standard solution (15, 30, 60, 125 and 250 µg/ml) was taken into tubes, containing 1.5mL ethanol. 0.1mL of KOH 1Molar was added to the flask. After 5 min, 0.1mL 10%  $AlCl_3$  and 2.8mL of distilled water were added to the mixture. The absorbance was noted at 415 nm using UV-Visible spectrophotometer (12).

#### **Results**

##### *Measurement of total flavonoid*

The total content of flavonoid in *Camellia sinensis* L. leaves extracts was  $9.54 \pm 0.68$  µg quercetin per each mg extract and the total flavonoid content of extract of *Cinnamomum verum* wood was  $8.27$  µg of quercetin in each mg extract.

##### *Changes in blood glucose levels and weight induced by green tea extract*

According to the experiments results, normal fasting blood glucose of rats in this experiment was determined as 95 mg/dl and the differences with this scale was estimated and compared.

As shown in Fig. 2, before two weeks of induction of diabetes in rats and with receiving the green tea extract, there isn't any significant difference among the groups in blood sugar levels, but after receiving the extract in the third week, significant difference at dose of 200 mg/kg of green extract with positive control has been observed ( $P < 0.01$ ) and at the 4<sup>th</sup> and the 6<sup>th</sup> weeks this significant difference was observed in all doses of green tea extract- ( $P < 0.001$ ) (Fig. 2).

Also changes in weight loss before the second week of receiving the extract was not significant, but in the third, fourth and sixth week of treatment, the differences were statistically significant (Fig. 3).

**Figure 4** Comparison of blood glucose levels (mg/dl) between cinnamon extract groups with a control group F1: control diabetic group ,F5: cinnamon extract 50 mg/kg F6: cinnamon extract 100 mg/kg F7: cinnamon extract 200 mg/kg,\* P < 0.05: significant difference compared to diabetic control group,\*\* P < 0.01: Significant difference compared to diabetic control group,\*\*\*P < 0.001: Significant difference compared to diabetic control group

**Figure 5** Comparison of mice body weight (mg) between cinnamon extract groups with a control group F1: control diabetic group, F2: cinnamon extract 50 mg/kg F3: cinnamon extract 100 mg/kg F4: cinnamon extract 200 mg/kg: \*  $P < 0.05$ : Significant difference compared to diabetic control group, \*\*  $P < 0.01$ : Significant difference compared to diabetic control group, \*\*\*  $P < 0.001$ : Significant difference compared to diabetic control group

**Figure 6** Comparison of blood glucose levels (mg/dl) between combination of cinnamon with green tea extract groups with a control group, F1: control diabetic group, F8: combination doses of cinnamon and green tea (50 mg/kg), F9: combination doses of cinnamon and green tea (100 mg/kg), F10: combination doses of cinnamon and green tea (200 mg/kg) \*  $P < 0.05$ : Significant difference compared to diabetic control group, \*\*  $P < 0.01$ : Significant difference compared to diabetic control group, \*\*\*  $P < 0.001$ : Significant difference compared to diabetic control group

*Changes in blood glucose levels and weight induced by cinnamon extract*

Before induction of diabetes and before the third week of receiving the cinnamon extract, there was not any significant differences among the groups according to blood sugar levels ( $P > 0.05$ ), and in the third week, the significant result was observed at dose of 100 mg/kg and at the 4<sup>th</sup> and the 6<sup>th</sup> week of treatment, this difference was significant for all three doses ( $P < 0.001$ ) (Fig. 4). For the weight gain induction, before the third week of receiving the extract, there was no significant differences among the groups ( $P > 0.05$ ) and in the third week, this difference was significant at dose of 100mg/kg and in the 4th and the 6th week, the results were significant in all three doses ( $P < 0.001$ ) (Fig. 5).

*Changes in blood glucose levels and weight induced by combined green tea, -cinnamon extract*

Figure 6 shows the results of combinational therapy of green tea and cinnamon extract and as it is shown, in the fourth and sixth weeks of treatments, the differences with control group were more profound significant in all doses ( $P < 0.001$ ) and in figure 7, the differences in body weight gain is exactly increased in the 4th and the 6th weeks.

*Comparison between EC<sub>50</sub> of the groups*

As shown in figures 8 and 9, the EC<sub>50</sub> of combinational therapy of cinnamon and green tea extracts decreased significantly blood glucose and gaining body weight after 6 weeks of treatment explain synergic effect between green tea and cinnamon.

**Figure 7** Comparison of mice body weight (mg) between cinnamon extract groups with a control group F1: control diabetic group, F2: cinnamon extract 50 mg/kg F3: cinnamon extract 100 mg/kg F4: cinnamon extract 200 mg/kg: \*  $P < 0.05$ : Significant difference compared to diabetic control group, \*\*  $P < 0.01$ : Significant difference compared to diabetic control group, \*\*\*  $P < 0.001$ : Significant difference compared to diabetic control group

## Discussion

This study compared the effects of three different routes of administration for green tea, cinnamon extract and combinational therapy of cinnamon extract and green tea, on blood glucose and body weight in diabetic rats. In all three categories of treatments, the extracts at doses of 50, 100 and 200 mg/kg reduced blood sugar and increased weight gain in the 4th and the 6th weeks of treatment in diabetic animals, and this improvement for combinational therapy regime was much more significant. Also considering the comparison of the results at the end of the sixth week, the dose of 200 mg/kg cinnamon extract - green tea was the most appropriate dose in vivo.

Mustata et al in a study, have reported that green tea therapy with vitamins E and C as antioxidant vitamins had no significant differences on glycemia, but inhibited the formation of hyperlipidemia and had improvement in retinal superoxide (12). Also, some other studies about the role of cinnamon in diabetes showed that it could reinforce insulin performance and improve insulin receptor phosphorylation (13,14). Previously, Polanski *et al.* reported that cinnamon contains some constituents as cinnamon oil, euoginol, thyme oil and cumarin contents which can enhance insulin secretion (15).

Tsubaki *et al.* showed that daily consumption of 1.5 g dried green tea powder in human diet was improved glucose tolerance in diabetics (16). In another study assaying combined effects of insulin and cinnamon, it was demonstrated that this therapeutically regime was more effective than each of them individually (17,18).

Our study's results confirmed it and had some similarity with those studies which have shown anti diabetic action for herbal drugs (16).

Although our experiment has shown that cinnamon and green tea reduced blood glucose levels in diabetic animals, it has not demonstrated that these herbal medicines are as effective in non-diabetic individuals. The main reason for the better improvement of blood glucose in combinational therapy of cinnamon and green tea extracts, may be because of the synergic effect of polyphenols found in green tea and cinnamon which improved glucose metabolism, reduced food intake and reduced oxidative stress by streptozotocin and these polyphenols may especially increase glucose metabolism and decrease insulin resistance in adipocytes. Also, cinnamon and green tea may able to increase insulin secretion from pancreatic Langerhans islets cells, too. According to recent study either cinnamon and green tea extract can decrease blood sugar and induce weight gain individually and has been observed to have synergic effect in an animal model of type-1 and with considering the absence of herbal profound hypoglycemic adverse effects,; this therapeutic regime can be suggested for the people with high risk of diabetes and as a complementary regime with anti-hyperglycemic drugs in diabetic patients. Besides, much more clinical trials are necessary to introduce these herbal extracts for diabetes therapeutics, especially with considering other biochemical parameters as their effect on insulin-blood levels and insulin-tolerance.
